Customer Journey Map

CrimeVision AI — Intelligent Multimodal Forensic Analysis Platform

DATE	29 October 2026	**PROJECT TYPE**	Individual / Solo	**PRIMARY USER**	Forensic investigator / authorized evidence analyst

Purpose. This journey map describes a plausible end-to-end experience for an authorized analyst using CrimeVision AI to review multimedia evidence. It distinguishes user actions and expectations from capabilities that may still be under development; it is a design model, not validated user research.

STAGE	1. PREPARE	2. IMPORT	3. ANALYZE	4. REVIEW	5. VERIFY	6. REPORT
USER GOAL	Define case scope and identify authorized files.	Select image, video, or audio evidence.	Run available detection or transcription tools.	Inspect outputs and locate relevant segments.	Compare findings with original evidence.	Save reviewed observations for documentation.

Journey at a glance: Prepare → Import → Analyze → Review → Verify → Report. The analyst remains responsible for validating observations against the original evidence.

Journey Detail

User actions, touchpoints, friction, and design opportunities across the six stages

JOURNEY DIMENSION	1. PREPARE	2. IMPORT	3. ANALYZE	4. REVIEW	5. VERIFY	6. REPORT
USER ACTIONS	Set case objective, access permissions, and review priorities.	Choose supported media; check file type, size, and quality.	Start the applicable pipeline: visual detection or audio transcription.	Read detections, annotated frames, transcript text, and available timestamps.	Replay or reopen source media; check context, accuracy, and false positives.	Select verified observations and prepare a clear summary for the case record.
TOUCHPOINTS	Case notes; local evidence directory; access controls (where implemented).	CrimeVision upload/selection interface and file validation (as implemented).	Flask/Python backend; OpenCV; YOLO/RT-DETR; Whisper; optional Groq API.	Results view, annotated images/video frames, transcript, timestamps if produced.	Original media player/viewer; model output; analyst notes.	Report/export interface or manually assembled report, depending on current implementation.
QUESTIONS / NEEDS	What am I looking for, and which files am I authorized to review?	Is this file supported, readable, and processed without alteration?	Which tools ran, and what input did each tool process?	What was detected or transcribed, and where in the source?	Can I independently confirm this observation in the original evidence?	Can another reviewer understand the result and its limitations?
PAIN POINTS	Unclear scope or inconsistent file organization.	Unsupported codecs, large files, poor lighting, noise, or corrupt media.	Slow processing on CPU; unavailable models or missing API configuration.	False detections, missed objects, transcription errors, or unclear timestamps.	Loss of context, ambiguous wording, or an AI-generated claim mistaken for fact.	Manual report preparation; incomplete provenance or audit information.
OPPORTUNITIES	Provide a concise case checklist and clear authorization reminder.	Show accepted formats, size limits, and processing status before analysis.	Display which pipeline ran, its model/tool, and any configuration failures.	Link results to source filenames, frame/time references, and confidence where available.	Offer side-by-side source review, editable notes, and explicit uncertainty labels.	Generate structured summaries with source references, tool details, and reviewer confirmation.
SUCCESS SIGNAL	A clear review objective and a manageable evidence set.	Files are accepted and associated with the correct case.	The applicable analysis finishes and reports failures clearly.	The analyst can locate candidate observations quickly.	Important observations are checked against the original source.	A traceable, human-reviewed summary is ready for documentation.

Experience principles

- **Human review first:** AI outputs are candidate observations, not autonomous forensic conclusions.
- **Traceability:** preserve file identity and source time/frame references wherever available; do not imply a complete chain of custody unless implemented and validated.
- **Separate modalities:** distinguish object-detection results from audio transcripts and optional LLM interpretations.
- **Honest system status:** indicate which tools actually ran, including CPU-only processing, missing configuration, or failed analysis.

Scope note: This map reflects the known setup and intended workflow: Flask/Python, OpenCV, YOLO/RT-DETR for visual detection, Whisper for audio transcription, optional Groq API assistance, and a planned Three.js visualization layer. UI, persistence, reporting, authentication, audit trail, and integrated multimodal fusion should be called implemented only after source-level verification.
